DA-R-EPOCH vs R-CHOP in DLBCL: How Do We Choose?

Ajay Major, MD, MBA, and Sonali M. Smith, MD
Section of Hematology/Oncology, The University of Chicago

Abstract: The emerging molecular and prognostic characterization of diffuse large B-cell lymphoma (DLBCL) has challenged the rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) treatment paradigm in recent years, with the identification of several DLBCL subtypes associated with significantly inferior survival after standard R-CHOP therapy. Efforts to improve upon the R-CHOP backbone have included dose intensification as well as the addition of new agents; the infusional dose-adjusted rituximab, etoposide, prednisone, vincristine, cyclophosphamide, and doxorubincin (DA-R-EPOCH) regimen has been identified as a potential replacement for R-CHOP in high-risk DLBCL. In this review, we provide a historical perspective on the R-CHOP and DA-R-EPOCH regimens and summarize the clinical trial literature regarding the efficacy of each regimen in various risk groups of DLBCL. Further, we propose clinical management scenarios in which DA-R-EPOCH may be preferred, including some for patient populations in which the use of R-CHOP vs DA-R-EPOCH is controversial.

Introduction

Diffuse large B-cell lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma (NHL) in the United States. Treatment with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) chemoimmunotherapy leads to a cure in 50% to 70% of patients. R-CHOP has been the therapeutic standard for DLBCL for nearly 20 years, with the addition of rituximab to the CHOP backbone in the 2000s significantly improving survival after decades of unsuccessful efforts to intensify CHOP with additional chemotherapeutics. However, DLBCL is increasingly being recognized as a heterogeneous disease with distinct molecular subtypes affecting both response and survival. As such, intense interest has been shown in improving upon the standard-of-care R-CHOP regimen, particularly for patients with adverse prognostic features or high-risk tumor genetics. One regimen in particular that has emerged is dose-adjusted rituximab, etoposide, prednisone, vincristine, cyclophosphamide, and doxorubincin (DA-R-EPOCH), an intensified infusional variation of R-CHOP that has been studied in numerous DLBCL subtypes. Herein, we review the history of the
R-CHOP and DA-R-EPOCH regimens and summarize the literature regarding their efficacy in various risk groups of DLBCL, including potential patient populations in which DA-R-EPOCH may be preferred and those in which controversy persists.

**Historical Perspective: Evolution of R-CHOP as the Standard of Care in DLBCL**

Multiagent chemotherapy for DLBCL was pioneered by DeVita and colleagues in 1975 with the publication of a series of 27 patients who were treated with 6 cycles of procarbazine, vincristine, prednisone, and either cyclophosphamide or nitrogen mustard, with an overall response rate (ORR) of 70% and a complete response (CR) rate of 41%. Long-term survival was demonstrated in the 37% of patients who were in remission 2 years after the completion of treatment, which the authors described as compatible with cure. These results were confirmed the following year in a randomized controlled trial by the Southwest Oncology Group of doxorubicin, vincristine, and prednisone (HOP) vs CHOP, which demonstrated a 1-year overall survival (OS) rate of 64% to 75%. The possibility of curing aggressive B-cell lymphomas with chemotherapy alone had not previously been demonstrated in that era, and it generated considerable enthusiasm for the development of novel multiagent combination chemotherapy regimens.

A series of intensified second- and third-generation regimens were developed in the 1980s, with the goal of improving response rates. These regimens, which relied on an increased number of cytotoxic agents, included methotrexate, bleomycin, doxorubicin, cyclophosphamide, vincristine, and dexamethasone (m-BACOD); prednisone, doxorubicin, cyclophosphamide, and etoposide, followed by cytarabine, bleomycin, vincristine, and methotrexate with leucovorin rescue (ProMACE-CytaBOM); and methotrexate, doxorubicin, cyclophosphamide, vincristine, prednisone, and bleomycin (MACOP-B). In several phase 2 trials, the CR rates with these regimens appeared significantly higher than those with first-generation regimens, such as CHOP, with a doubling of historical OS rates. Given the apparent superiority of these next-generation regimens in cross-trial comparisons, the Southwest Oncology Group and the Eastern Cooperative Oncology Group initiated a prospective, randomized phase 3 trial of CHOP, m-BACOD, ProMACE-CytaBOM, and MACOP-B in 1986. In this study of 899 patients with advanced-stage, intermediate- or high-grade NHL, no significant difference in ORR, CR rate, disease-free survival rate, or OS rate was found among any of the 4 regimens, with a 3-year OS rate of 54% for CHOP. However, the rates of grade 4 to 5 toxicities were significantly higher with m-BACOD and MACOP-B than with CHOP, and the third-generation regimens did not improve survival over CHOP in any of the prognostic subgroups. This landmark study established CHOP as the standard-of-care regimen for DLBCL because it was effective and conferred the least toxicity. The study also challenged the notion that “more is better” with respect to the chemotherapy-based management of DLBCL.

However, long-term cure rates were still relatively poor with CHOP, at less than 50%, particularly for adverse-risk subgroups identified by the International Prognostic Index (IPI) in 1993. As such, calls were renewed for novel, non-chemotherapeutic approaches to the treatment of DLBCL, including monoclonal antibodies. The introduction of rituximab in a phase 1 study in 1994 quickly led to subsequent phase 2 studies that demonstrated considerable activity of rituximab as a single agent and in combination with CHOP in both untreated and relapsed DLBCL. R-CHOP was solidified as the new standard of care in DLBCL after the publication of several phase 3 trials, the first in 2002 by Coiffier and colleagues; in this study, 398 elderly patients aged 60 to 80 years with untreated DLBCL were treated with 8 cycles of CHOP vs R-CHOP. The patients treated with R-CHOP had significantly higher rates of CR (76% vs 63%) and 2-year OS (70% vs 57%), with no significant differences in rates of adverse events between R-CHOP and CHOP. The superiority of R-CHOP in younger patients was confirmed in a study from the MabThera International Trial (MInT) Group published by Pfreundschuh and colleagues in 2006, in which 824 patients aged 18 to 60 years with DLBCL and a maximum IPI score of 1 were treated with 6 cycles of CHOP-like therapy vs rituximab plus CHOP-like therapy. R-CHOP treatment resulted in significantly higher CR rates (86% vs 68%) and 3-year OS rates (93% vs 84%), with similar rates of toxicity. Long-term follow-up from both studies confirmed the superiority of R-CHOP and the ability to cure patients with this regimen, with 10-year OS rates of 44% vs 28% in elderly patients and 6-year OS rates of 90% vs 80% in younger patients. Several other studies have confirmed the survival advantage of R-CHOP over CHOP.

Despite these high OS rates, R-CHOP is less effective at inducing short- and long-term remissions in some patients who have DLBCL, with approximately 20% of them having primary refractory disease and 30% subsequently experiencing relapse after achieving a complete remission. Although previous attempts in the 1980s to improve the rates of response to the CHOP backbone via chemotherapy had been unsuccessful, the development of the infusional EPOCH regimen in the 1990s provided a...
novel and rational treatment paradigm that would challenge the R-CHOP status quo.

The Rationale and Development of Infusional DA-R-EPOCH in DLBCL

The development of the EPOCH regimen by the National Cancer Institute (NCI) began after in vitro studies of the individual components of CHOP chemotherapy found that less resistance to chemotherapy developed in tumor cells with prolonged low-concentration exposure to vincristine and doxorubicin than with short-duration bolus administration, and etoposide was found to be synergistic with CHOP. With these data, a 96-hour continuous infusion regimen of EPOCH was designed that incorporated a dose-adjustment strategy based on the hematopoietic nadir to account for interpatient variations in steady-state plasma concentrations—hence the “dose-adjusted” nomenclature.

EPOCH was first studied in 74 patients with relapsed or refractory low-, intermediate-, or high-grade NHL. In the preliminary phase 2 report by Wilson and colleagues, published in 1993, patients with intermediate- or high-grade lymphoma had ORRs of 77% to 90%, with CRs in 20% to 42%. In a report published in 2000, the 8-year follow-up data for the cohort demonstrated an ORR of 70% to 78% and a CR rate of 13% to 36% for patients with aggressive lymphomas. At a median follow-up of 76 months, the OS was 12.6 months for patients with aggressive de novo lymphomas and 23.4 months for those with aggressive transformed lymphomas in the relapsed and refractory setting, with improved outcomes for EPOCH compared with other salvage regimens used at the time in cross-trial comparisons.

EPOCH was quickly brought into the front-line setting by 2002 in a phase 2 study of 50 patients with newly diagnosed DLBCL, which demonstrated an ORR of 100% and a CR rate of 92%, as well as an OS rate of 73% at a median follow-up of 62 months. Subset analyses revealed no difference in response or survival rates according to IPI score, with an ORR of 100% in high-risk patients who had an IPI score of 3 to 5, but they revealed that overexpression of the BCL2 protein, a marker of the activated B-cell (ABC) subtype, was associated with inferior survival. The addition of rituximab to EPOCH was also examined in a phase 2 study by the NCI that was published in 2002, in which 38 patients with untreated or relapsed/refractory aggressive lymphomas received at least 6 cycles of DA-R-EPOCH. The study cohort included a significant number of high-risk patients, with 61% of the untreated patients having at least high-intermediate IPI scores and 30% having a performance status of 2 or higher. The untreated patients had an ORR of 85% and a 1-year OS rate of 79%, which was encouraging given the preponderance of patients with high-risk IPI scores in the study. These early studies generated considerable enthusiasm for DA-R-EPOCH as a possible replacement for R-CHOP in DLBCL with a high-risk IPI score.

Improving Upon R-CHOP as the Standard of Care

The majority of phase 3 clinical trials for DLBCL over the past decade have focused on improving the R-CHOP backbone through treatment intensification or the addition of novel agents, including the use of precision medicine to determine which agents may be most appropriate for patients with specific molecular subtypes of DLBCL.

Intensifying Standard R-CHOP-21

Early research in the R-CHOP era, including the aforementioned MInT Group study, identified that patients with high IPI scores had an inferior response to standard R-CHOP. The MInT Group study found a significantly worse 3-year event-free survival (EFS) rate (76%) in patients with an IPI score of 1 and/or bulky disease than in those without these adverse characteristics (89%). Given the prognostic validity of the IPI score in the rituximab era, with a 5-year OS rate of less than 50% for high-risk patients compared with a rate of more than 90% for low-risk patients, extensive attempts have been made to intensify the standard 21-day R-CHOP (R-CHOP-21) regimen for patients with high-risk IPI scores.

Although most phase 3 intensification studies did not demonstrate improvements in survival over R-CHOP-21 (Table 1), limited evidence suggests that treatment intensification can improve survival in very select populations. In a randomized trial conducted by the French Groupe d’Etude des Lymphomes de l’Adulte, which compared rituximab, doxorubicin, cyclophosphamide, vincristine, bleomycin, and prednisone (R-ACVBP) vs R-CHOP, an OS benefit was observed in patients aged 18 to 59 years with an age-adjusted IPI score of 1 who were treated with R-ACVBP, with 3-year OS rates of 92% vs 84%. However, the trial evaluated a very narrow patient population, and the rates of short- and long-term toxicities were higher in the R-ACVBP arm, with a 38% rate of febrile neutropenia (vs 9% in the R-CHOP group) and an increase in secondary malignancies. Further post hoc analysis of this study revealed that R-ACVBP was superior to R-CHOP only in patients with the non-germinal center B-cell (non-GCB) subtype of DLBCL.

The limited toxicity and extended anti-lymphoma activity of rituximab were the focus of several studies to intensify rituximab administration with R-CHOP,

</table>
including several phase 2 trials of dose-dense rituximab with R-CHOP that suggested improved survival in elderly patients with a poor prognosis.\(^{35,46}\) However, subsequent randomized phase 3 data on R-CHOP with weekly rituximab found no difference in survival with intensified rituximab and greater toxicity in older patients. Overall, the intensification of standard R-CHOP-21 to treat DLBCL in both unselected patients and those with high-risk IPI scores has been unsuccessful in improving outcomes.

**Precision Medicine and R-CHOP: the XR-CHOP Paradigm**

Given the limited success in improving R-CHOP outcomes by means of classic risk stratification with the
IPI score, intense interest is being shown in designing new treatment regimens based on specific subtypes of DLBCL, moving toward the use of precision medicine in lymphoma. Gene expression profiling has demonstrated 2 distinct subtypes of DLBCL based on the cell from which the lymphoma originated during the process of B-cell differentiation: germinal center B-cell (GCB) lymphoma and activated B-cell (ABC) lymphoma.\(^\text{47}\) The prognosis for ABC DLBCL is significantly worse than that for GCB DLBCL after R-CHOP treatment, with 5-year OS rates of 45% to 56% in the ABC subtype vs 78% to 80% in the GCB subtype.\(^\text{48}\) Further, there are molecular subtypes of DLBCL, which also confer a worse prognosis. In the latest World Health Organization (WHO) guidelines, the entity “high-grade B-cell lymphoma” refers to the identification of MYC, BCL2, and BCL6 rearrangements by fluorescence in situ hybridization (FISH), with the presence of MYC and BCL2 or BCL6 rearrangements referred to as “double-hit lymphoma” (DHL) and the presence of all 3 rearrangements referred to as “triple-hit lymphoma” (THL).\(^\text{49}\) In large retrospective series, both DHL and THL confer a very poor prognosis when treated with standard R-CHOP therapy, with 5-year OS rates of 22% to 27%.\(^\text{49}\) Lymphomas that co-express MYC and BCL2 proteins by immunohistochemistry without underlying rearrangements, colloquially termed “double-expressor lymphomas” (DELs), are also an adverse prognostic group with an inferior 5-year OS rate of 30% to 36% when treated with R-CHOP.\(^\text{49}\)

Given these inferior outcomes, recent trials have focused on developing novel regimens that are based on the cell of origin or molecular subtype of DLBCL, often by using an “XR-CHOP” framework in which a new therapeutic (“X”) is added to the R-CHOP backbone.\(^\text{50,51}\) As shown in Table 1, these phase 3 studies have also had limited success, with no improvement in survival for the non-GCB/ABC subtype of DLBCL after the addition of bortezomib, lenalidomide (Revlimid, Celgene), or ibrutinib (Imbruvica, Pharmacycics/Janssen) to R-CHOP.

Other novel agents are in development and have shown promising activity; for example, the BCL2 inhibitor venetoclax (Venclexta, AbbVie) was added to R-CHOP in a recently reported phase 2 study in which 28% of patients had ABC DLBCL.\(^\text{52}\)

### Challenging R-CHOP With DA-R-EPOCH to Create a New Standard of Care

Given the limited success of R-CHOP intensification and XR-CHOP in improving outcomes for patients who have DLBCL with high-risk clinical and molecular features, DA-R-EPOCH has emerged as a potential new treatment backbone, with numerous studies conducted over the past decade.\(^\text{26,53-60}\) These trials have been primarily in the phase 2 setting and have focused on the use of DA-R-EPOCH in specific high-risk DLBCL cohorts (see eTable at www.hematologyandoncology.net).

### Clinical and Biological Scenarios in Which DA-R-EPOCH Is Preferred

#### High-Grade B-Cell Lymphoma With DHL/THL

Informed by several retrospective studies demonstrating better outcomes with intensified therapy in patients having high-grade DLBCL with rearrangements indicating a poor prognosis,\(^\text{61,62}\) a phase 2 trial evaluating DA-R-EPOCH in patients with MYC-rearranged DLBCL was conducted by the NCI.\(^\text{63}\) At a median follow-up of 14 months for the first 52 patients, the progression-free survival (PFS) rate was 79% for the whole cohort and 87% for patients with DHL, which were promisingly high survival rates with DA-R-EPOCH. However, not all patients in the trial had DHL, and some patients had Burkitt lymphoma. A subsequent meta-analysis of R-CHOP vs dose-intensive therapies in DHL, which included 11 retrospective analyses but no randomized controlled studies, found a significantly longer PFS but not OS in patients with DHL treated with frontline DA-R-EPOCH than in those treated with R-CHOP.\(^\text{64}\) The final results of the aforementioned NCI phase 2 study were published in 2018 and demonstrated a 4-year OS of 77% for all patients who had MYC-rearranged DLBCL treated with DA-R-EPOCH.\(^\text{53}\) Of the 53 patients in the final analysis, 45% had DHL, and the 4-year OS rate of the patients who had DHL was 82%, with a 4-year OS rate of 72% in the patients who had DHL with high IPI scores of 3 to 5. Although this was a phase 2 single-arm study, it demonstrated the highest long-term survival rates of patients with high-risk DHL in the modern era and led to the inclusion of DA-R-EPOCH in the National Comprehensive Cancer Network (NCCN) guidelines.

However, a recent large retrospective review of more than 6800 patients with MYC-rearranged DLBCL, DHL, or THL who were treated with R-CHOP or DA-R-EPOCH demonstrated no difference in 4-year OS between the 2 regimens.\(^\text{65}\) Overall, the evidence for the efficacy of DA-R-EPOCH in DHL/THL is limited, but it is frequently administered at lymphoma centers owing to the known poor outcomes with standard R-CHOP.

#### Primary Mediastinal B-Cell Lymphoma

Primary mediastinal B-cell lymphoma (PMBL) is a rare subtype of NHL that was previously thought to be a subtype of DLBCL, although it has now been recognized as a unique disease that shares some features with Hodgkin lymphoma.\(^\text{66}\) R-CHOP has historically been the mainstay of therapy, with 3-year EFS rates of 78%\(^\text{67}\) and 5-year OS rates of...
HIV-Associated DLBCL. Most patients with HIV-associated NHL have advanced-stage DLBCL or Burkitt lymphoma, and their prognosis is poor compared with that of HIV-negative patients; their median survival was 5 to 6 months in the pre-antiretroviral therapy (ART) era and is approximately 2 years with CHOP chemotherapy. However, the risk for treatment-related mortality was significantly higher with the addition of rituximab to CHOP than with CHOP alone in a phase 3 randomized trial in 2005, particularly in patients with a CD4 cell count of less than 50/µL. This finding significantly dampened interest in R-CHOP for the treatment of HIV-associated DLBCL, and EPOCH was therefore explored for these patients, with a trial in 2003 demonstrating an OS rate of 60% for EPOCH at a median follow-up of 53 months. Subsequent studies found that outcomes for HIV-associated NHL were significantly improved in the era of ART and that rituximab could be safely given concurrently with ART to improve survival. A landmark phase 2 randomized study in 2010 by Sparano and colleagues administered EPOCH with either concurrent or sequential rituximab to 106 patients with untreated HIV-associated aggressive lymphoma; the 2-year OS rate was 70% with concurrent DA-R-EPOCH, and 70% to 75% of the surviving patients were without evidence of progressive lymphoma at 2 years. Notably, the rate of treatment-associated deaths was 7.3% to 9.8% in the study, lower than the 14% in the aforementioned R-CHOP vs CHOP study. A subsequent analysis of pooled data from 1546 individual patients in 19 prospective clinical trials of HIV-associated NHL found a significantly improved OS with EPOCH compared with CHOP, although the difference in OS was of only borderline significance when DA-R-EPOCH was compared with R-CHOP. In the absence of robust randomized data, many centers utilize DA-R-EPOCH for HIV-associated DLBCL, and it is the preferred regimen in the NCCN guidelines, particularly for patients with other adverse risk factors, such as a high IPI score, DEL, or DHL. However, R-CHOP is also a reasonable therapeutic choice.

Gray Zone Lymphoma. Gray zone lymphoma (GZL) is a very rare and distinct lymphoma having pathologic features of both DLBCL and classic Hodgkin lymphoma (cHL), with a more aggressive presentation and inferior outcomes in comparison with DLBCL and cHL. Although GZL has historically been treated with both DLBCL and cHL paradigms, outcomes are superior when it is treated with R-CHOP or DA-R-EPOCH, for which the 2-year PFS rate is 52%, compared with 22% for cHL-type therapy. A prospective study of DA-R-EPOCH in 24 patients with untreated mediastinal GZL found a 3-year EFS rate of 62% and a 3-year OS of 74%, which are better than historical survival rates and have led to the use of DA-R-EPOCH for GZL.

Clinical and Biologic Scenarios in Which DA-R-EPOCH vs R-CHOP Is Controversial

Patients With High-Risk IPI Scores. With data from the initial studies and an observational study in 2007, suggesting that DA-R-EPOCH may have particular activity in patients who have high-risk IPI scores, a phase 2 study of DA-R-EPOCH in 72 patients with untreated stage II or higher DLBCL was published by the NCI in 2008. The authors of this landmark study included per protocol assessments of the expression of several biomarkers, including CD10, BCL6, and MUM1, to determine GCB or ABC subtype, as well as the expression of BCL2, given the inferior survival with DA-R-EPOCH in their previous 2002 study. The study cohort included a substantial proportion of high-risk patients, with 40% of them having an IPI score of 3 or higher. The CR rates were 100% in patients with low IPI scores (0-2) and 82% in those with high IPI scores (3-5), with a lower 5-year survival rate of 74% in the patients with an IPI score of 3 and 37% in those with an IPI score of 4 or 5, compared with 90% to 100% in those with an IPI score of 0 to 2. A difference of borderline significance was found between the 5-year OS rates of patients with ABC DLBCL (P=0.059), although the difference in 5-year PFS was not significant. The authors concluded that DA-R-EPOCH may be more effective than R-CHOP for patients with GCB DLBCL as well as for patients with an IPI score of 0 to 2, and they also stated that the lower survival rate of the patients with high IPI scores was due to 4 deaths without progression. However, it is important to note that historical 5-year OS rates in the R-CHOP era were 67% for those with an IPI score of 3 and 54% for those with an IPI score of 4 or 5.
so DA-R-EPOCH was not associated with a significant improvement in these patients with high-risk IPI scores.

However, subsequent studies in HIV-associated DLBCL and MYC-rearranged DLBCL, which enrolled large proportions of patients with high IPI scores, generated renewed interest in evaluating DA-R-EPOCH for patients with high-risk IPI scores. A phase 2 study by the Spanish PETHEMA Group evaluated 81 patients with untreated, poor-risk DLBCL, 86% of whom had high-risk IPI scores of 3 to 5. The CR rate was 80% and the 10-year OS rate was 64%, with no significant difference in survival on the basis of IPI score or GCB vs ABC subtype. Toxicity was as previously described with DA-R-EPOCH; an episode of neutropenic fever developed in 46% of the patients, although 91% received all planned cycles. The 10-year OS rate in this study of patients with high-risk IPI scores was the highest described in the literature at the time, supporting further evaluation.

The Intergroup phase 3 randomized study of R-CHOP vs DA-R-EPOCH for untreated DLBCL enrolled 524 patients over an 8-year period from 2005 to 2013. A total of 491 eligible patients were randomly assigned to 6 cycles of either R-CHOP or DA-R-EPOCH. Most patients had advanced-stage disease, although the proportion of enrolled patients with a high-risk IPI score was much smaller than in previous studies of DA-R-EPOCH; 25% of the patients had an IPI score of 3, and 12% had an IPI score of 4 or 5. Evaluating for DHL or DEL was not prospectively required, and only a minority of patients were subsequently found to have either DEL (16%) or DHL (3 patients). At a median follow-up of 5.2 years, no significant differences were found in response rates or survival rates between the R-CHOP or DA-R-EPOCH cohorts; the 5-year OS rates were 79% for R-CHOP and 78% for DA-R-EPOCH. Post hoc subgroup analyses revealed a significantly higher PFS rate in the patients in the DA-R-EPOCH group with an IPI score of 3 to 5 without a significant difference in OS. No other subgroup differences in survival were noted.

ABC, activated B-cell; DA-R-EPOCH, dose-adjusted rituximab, etoposide, prednisone, vincristine, cyclophosphamide, and doxorubicin; DEL, double-expressor lymphoma; DHL, double-hit lymphoma; DLBCL, diffuse large B-cell lymphoma; GCB, germinal center B-cell; GZL, gray zone lymphoma; IPI, International Prognostic Index; OS, overall survival; PMBL, primary mediastinal B-cell lymphoma; R-CHOP, rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone; THL, triple-hit lymphoma; y, year(s).
between the patients who received R-CHOP and those who received DA-R-EPOCH, including no difference for the patients with DEL. Toxicity was significantly worse with DA-R-EPOCH; grade 3 to 5 adverse events developed in 98% of patients in the DA-R-EPOCH arm vs 78% in the R-CHOP arm. Although the efficacy of R-CHOP and DA-R-EPOCH did not differ in this study, there are concerns that the study cohort overrepresented favorable-risk patients, which may have obscured any benefit of DA-R-EPOCH. This is evidenced by a 3-year PFS rate in the control arm of 72%, which is higher than expected, as well as a lower number of patients with DEL in the study than expected and very few patients with DHL/THL. An initial requirement of fresh frozen tissue for study enrollment may have exacerbated this selection bias because patients with high-risk disease, for whom rapid progression is a concern, were likely not enrolled owing to an urgent need for the initiation of treatment.

As such, R-CHOP has remained the standard for the unselected frontline treatment of patients with DLBCL, including those with high-risk IPI scores, the aforementioned phase 3 study having been unable to answer questions about the utility of DA-R-EPOCH in DEL or DHL/THL owing to low patient numbers.

Activated B-Cell Subtype DLBCL. Given the poor prognosis of patients with ABC DLBCL, several studies have focused on evaluating the DA-R-EPOCH platform specifically for this subtype. On the basis of a greater understanding of CARD11 and MYD88 mutations in ABC DLBCL, the NCI added bortezomib to EPOCH without rituximab in 49 patients with relapsed DLBCL and found a significantly higher response rate and median OS in those who had ABC DLBCL than in those who had GCB DLBCL with the addition of bortezomib. However, subsequent phase 2 studies have diminished enthusiasm for DA-R-EPOCH in ABC DLBCL, such as the Cancer and Leukemia Group B (CALGB) study of 69 patients with untreated DLBCL that included an assessment of cell of origin. In that study, 51% of the patients had non-GCB/ABC DLBCL, and time to progression, EFS, and OS were all significantly worse in non-GCB than in GCB DLBCL after treatment with DA-R-EPOCH. Subsequent research on the management of ABC DLBCL has shifted to novel agents in an XR-CHOP platform, as detailed in Table 1.

Double-Expressor Lymphoma. As previously outlined, the phase 3 NCI-sponsored study of R-CHOP vs DA-R-EPOCH did not demonstrate a difference in survival for patients with DEL, although this conclusion was made in a post hoc subgroup analysis in a study that included very few patients with DEL. Retroactive analyses have confirmed this finding and as such, R-CHOP has remained the standard of care for DEL.

Richter Syndrome. The most common histology in patients with Richter syndrome is DLBCL. The prognosis for patients with Richter syndrome is extremely poor, with a median OS of 9 months in the modern era. R-CHOP is most commonly used for these patients, and retrospective analyses have suggested that DA-R-EPOCH does not significantly improve outcomes and may be associated with worse toxicity, with 73% of patients experiencing an adverse event in the first cycle and 30% dying without progression of lymphoma in one study of 46 patients. However, preliminary results of a phase 2 trial of venetoclax plus DA-R-EPOCH for Richter syndrome found a median OS of 16.3 months in 27 patients, and more data are needed.

Testicular DLBCL. Primary testicular lymphoma, which is histologically DLBCL in the majority of cases, is a rare extranodal NHL that has inferior OS compared with nodal DLBCL, with no plateau in survival curves and continual late relapses for more than 10 years after diagnosis. The current standard of care for patients with limited-stage disease involves orchiectomy, 6 cycles of R-CHOP, central nervous system (CNS) prophylaxis (given the high risk for CNS relapse), and contralateral scrotal radiation therapy to prevent contralateral testicular recurrence. None of the retrospective series of patients who had testicular DLBCL treated with intensified regimens such as DA-R-EPOCH have demonstrated an advantage over R-CHOP.

Current Landscape of DLBCL Management

Despite intensive study over the past 40 years and the identification of novel subtypes of disease with adverse risk factors, the management of DLBCL has remained relatively unchanged in the R-CHOP era, with standard R-CHOP effecting a cure in the majority of patients. Although intensified treatment with DA-R-EPOCH is another treatment option studied in some subtypes of DLBCL, the recent negative phase 3 trial of R-CHOP vs DA-R-EPOCH in the frontline setting has solidified the position of R-CHOP as the therapeutic standard and has unfortunately left several questions unanswered regarding high-risk subsets such as DEL and DHL/THL. DA-R-EPOCH is also more costly and more toxic than R-CHOP features that further call into question its utility for most patients with DLBCL. The evidence-based use of R-CHOP vs DA-R-EPOCH for various subtypes of DLBCL is summarized in Table 2, with phase 2 single-arm studies in DHL/THL, PMBL, HIV-associated
DLBCL, and GZL suggesting that DA-R-EPOCH can be used. It is important to note that considerable controversy surrounds these data, as most of the trials included unselected patients with DLBCL and lacked a comparator arm or had inadequate power to evaluate efficacy in specific high-risk subsets. Further, time-dependent selection bias in clinical trials, in which patients with aggressive presentations cannot be enrolled owing to trial requirements for tissue biopsies or cell of origin testing, may skew data. As such, standard R-CHOP is an appropriate alternative in all of these scenarios, particularly for patients who are unlikely to be able to tolerate more intensive and toxic DA-R-EPOCH.

Complicating the selection of an initial treatment for DLBCL is the emerging evidence of molecular heterogeneity in this disease. Although cell of origin provided initial insight, currently at least 8 groups of molecularly distinct subsets in DLBCL are known, increasing our appreciation of pathogenic heterogeneity. Further, the effect of TP53 mutations on treatment choice is undergoing active study, as TP53 mutations are independently associated with inferior outcomes of treatment with R-CHOP, but not DA-R-EPOCH. Studies to address these gaps in the literature are urgently needed, and numerous trials are in progress evaluating additions to the DA-R-EPOCH backbone, including lenalidomide plus DA-R-EPOCH in DHL and DEL, venetoclax plus DA-R-EPOCH in aggressive NHL, and acalabrutinib (Calquenue, AstraZeneca) with either R-CHOP or DA-R-EPOCH in DLBCL. Enrollment in clinical trials is paramount for patients who have DLBCL with adverse clinical or pathologic features, particularly trials of novel agents with robust biological rationales.

Disclosures
Dr. Major and Smith have no relevant conflicts of interest for this manuscript. In the past 36 months, Dr. Smith has served as an ad hoc consultant for Gilead, MorphoSys, ADC Therapeutics, BMS, Janssen, Karyopharm Therapeutics, Genentech, Celgene, TG Therapeutics, and Bayer.
